# Hybrid-Model Predictions

# Dataset

## Pittsburgh

- 50,893 reviews
- 987 restaurants
- 3192 users
- Users > 20 reviews
- Faster testing and debugging

## Las Vegas

- 158,880 reviews
- 8309 restaurants
- 5272 users
- Users > 50 reviews
- Proof of models built

### Yelp Open Dataset

An all-purpose dataset for learning

The Yelp dataset is a subset of our businesses, reviews, and user data for use in personal, educational, and academic purposes. Available as JSON files, use it to teach students about databases, to learn NLP, or for sample production data while you learn how to make mobile apps.

$$X_{32} = (a, b, c) \cdot (e, f, g) = a * e + b * f + c * g$$

rating prediction

$$\hat{r}_{ui} = p_u^T q_i$$

item preference vector

user preference vector

# Model Based

The diagram illustrates the cost function for a model-based recommendation system. The central equation is 
$$\min \sum_{(u,i) \in D} (r_{ui} - p_u^T q_i)^2 + \lambda(\|P\|^2 + \|Q\|^2)$$
 Four callout boxes provide context: 'minimizing cost function' points to the min operator; 'known rating entries' points to the summation index  $(u,i) \in D$ ; 'squared error:  $e$ ' points to the term  $(r_{ui} - p_u^T q_i)^2$ ; and 'regularization to prevent overfitting' points to the term  $\lambda(\|P\|^2 + \|Q\|^2)$ .

minimizing cost function

known rating entries

squared error:  $e$

regularization to prevent overfitting

$$\min \sum_{(u,i) \in D} (r_{ui} - p_u^T q_i)^2 + \lambda(\|P\|^2 + \|Q\|^2)$$

Algorithms to minimize cost function

1. Stochastic Gradient Descent (SGD)

$$q_i = q_i + \alpha(2ep_u + \lambda q_i)$$
$$p_u = p_u + \alpha(2eq_i + \lambda p_u)$$

2. Alternating Least Squares (ALS)

# Collaborative-Filtering Based Models

- User-Based CF

Focuses on taking people who have rated similarly to a user, and predicting rating depending upon how others have rated that item

- Item-Based CF

Focuses on taking items which are similar to the given item, and predicting rating depending on those items ratings as given by the user

# Review-Based Model

## Construction of Business Matrix

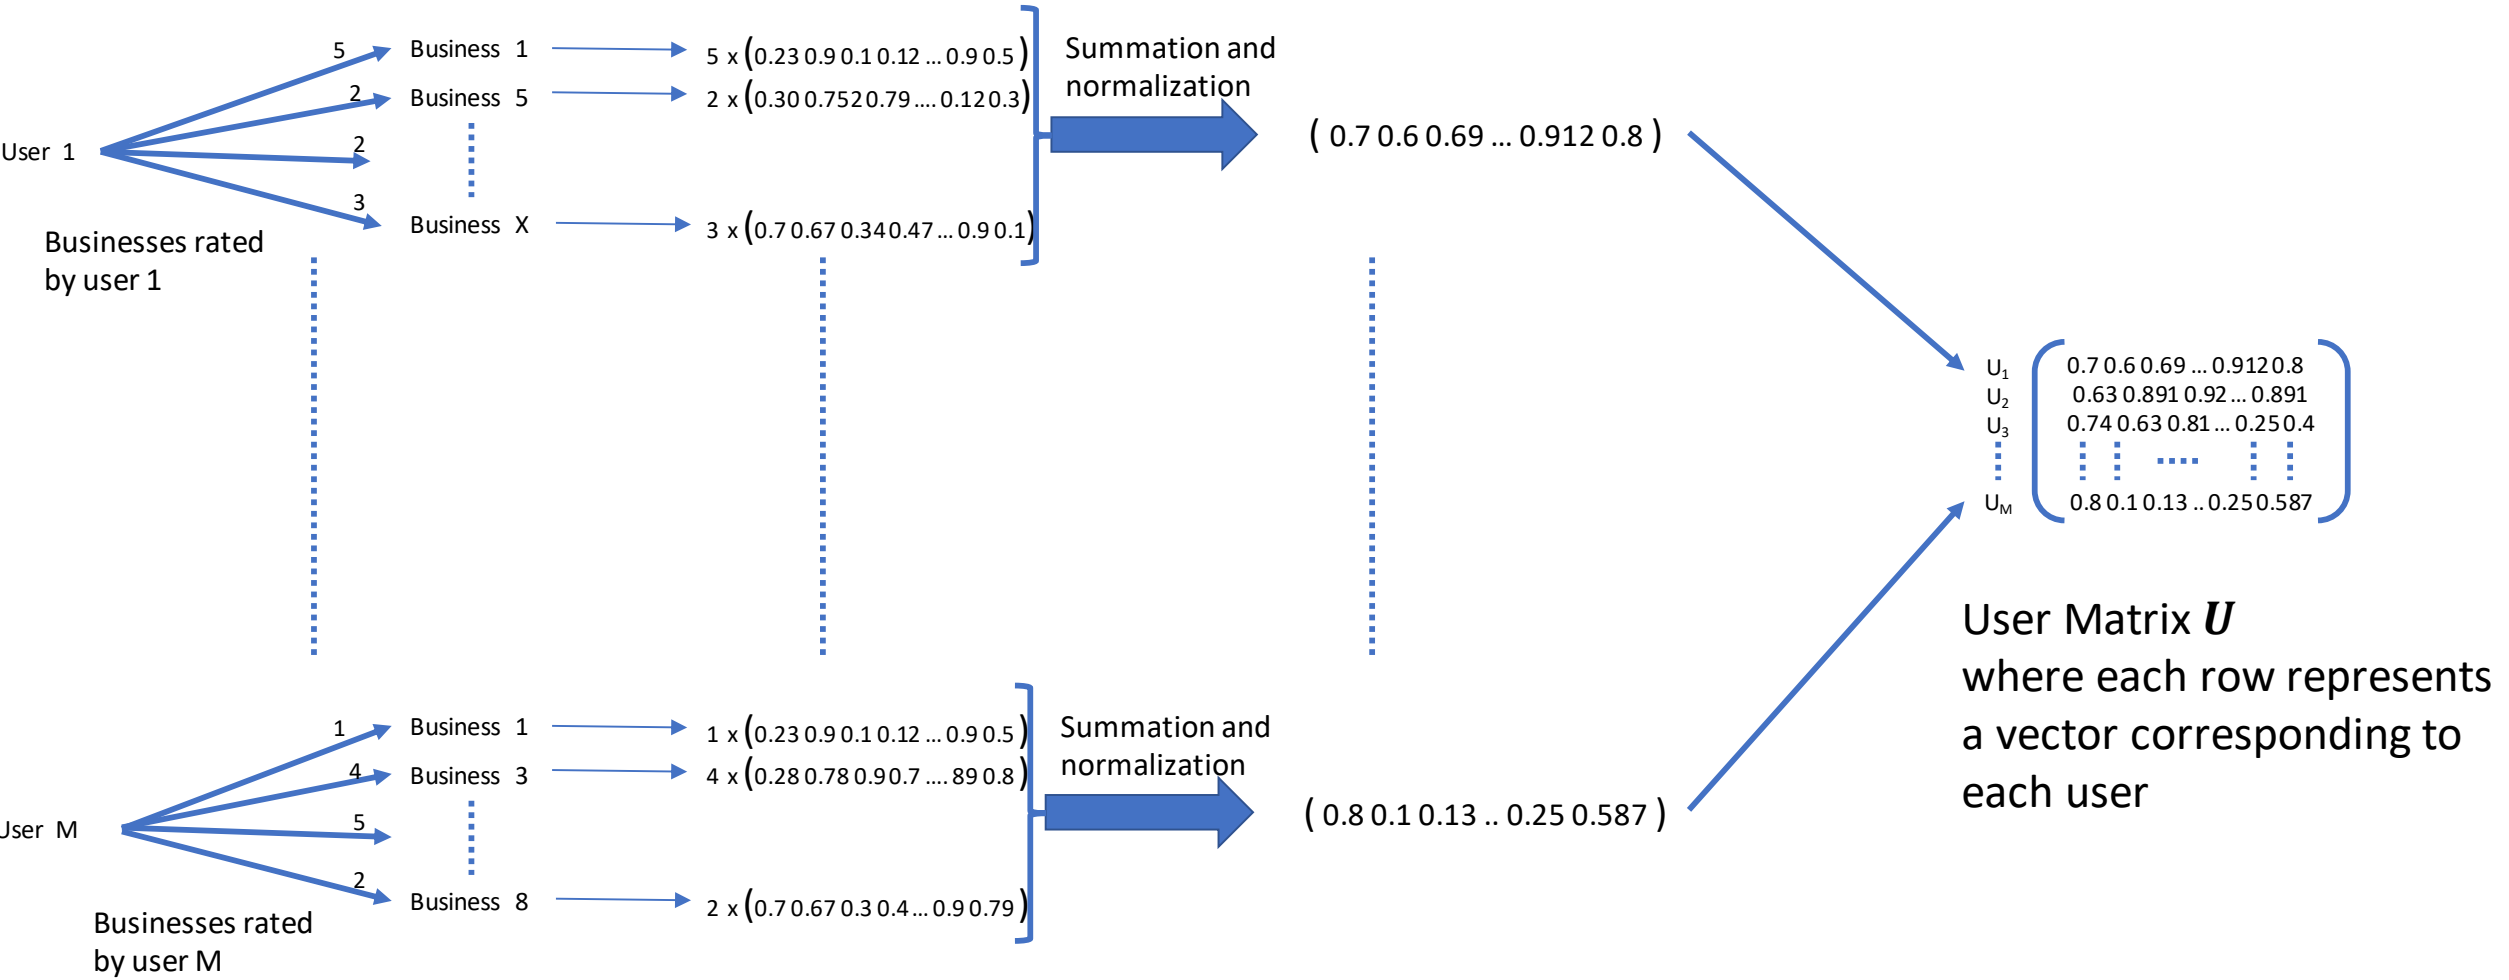

Business Matrix  $B$   
where each row represents  
a vector corresponding to  
each business

B <sub>1</sub>	0.23	0.9	0.1	0.12	...	0.9	0.5
B <sub>2</sub>	0.81	0.63	0.89	...	0.89	1	0.4
B <sub>3</sub>	0.74	0.63	0.9	...	0.97	0.245	
⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮
B <sub>N</sub>	0.23	0.9	0.1	0	...	0.908	0.14

Business Matrix **B**

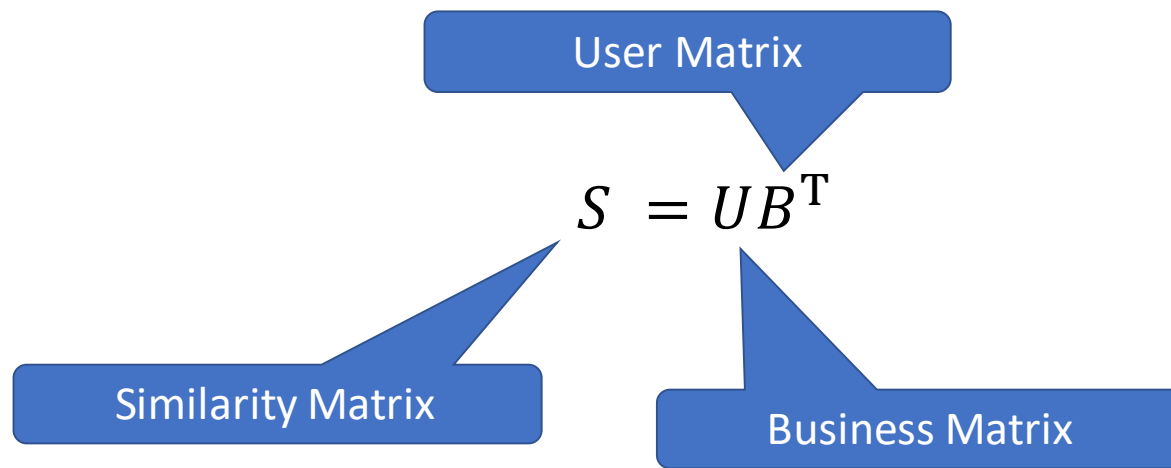

# Review-Based Model

## Construction of User Matrix

# Review Based

- To compute the cosine similarity between a User and a Business we compute  $S \in R^{I \times Q}$  ( $I$  unique Businesses and  $Q$  unique Users) by,

	$B_1$	$B_2$	$B_3$	$B_4$	$B_5$
$U_1$	-0.12	0.76	-0.56	0.33	0.36
$U_2$	0.37	0.21	0.45	0.36	-0.98
$U_3$	0.83	-0.25	.074	0.11	0.65
$U_4$	0.26	0.52	0.73	-0.84	0.36
$U_5$	-0.64	0.28	0.57	0.18	0.82

- To transform the similarity values  $(-1,1)$  into ratings  $(1,5)$  we build a regression model to regress ratings over similarity values.

# Text-Based Model

- We compute the Business Matrix  $B$  similar to Review-based Model we discussed earlier.
- Here we follow the similar approach to compute the User Matrix  $U$  as we did for the Business Matrix.
- Rest we follow the same procedure as in Review Based Model once we have User and Business Matrices.
- We compute the similarity matrix  $S = UB^T$ ,  $S \in R^I \times Q$  and regress ratings over similarity values.

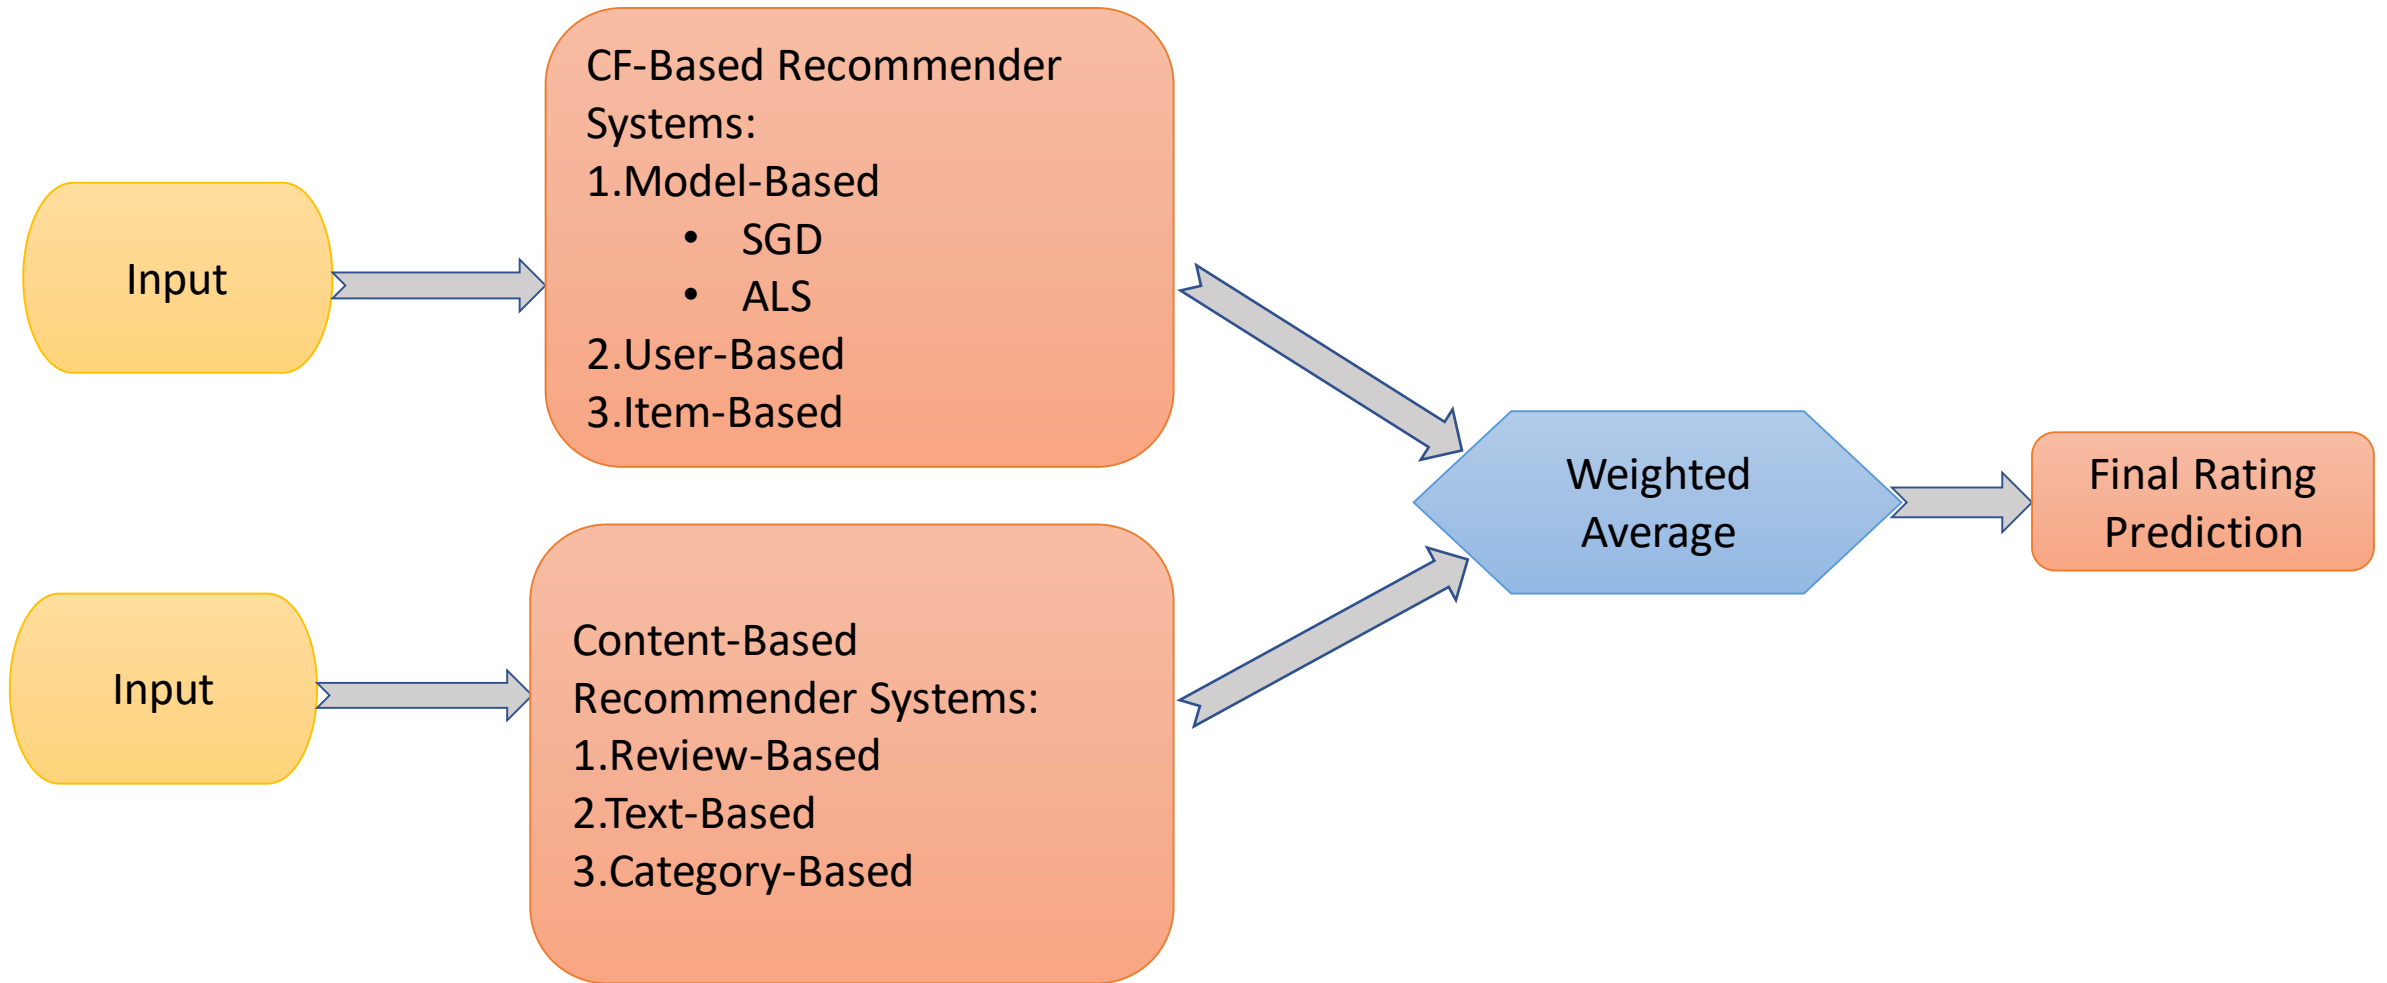

# Category-Based Model

- This method is similar to Review-based Model with different input.
- In Review-based Model we used the review as the input here we use business specific information as features.

```
Old_string =

# Hybrid-Model Predictions (RECAP)

# Results

## RMSEs for Pittsburgh

## RMSEs for Las Vegas

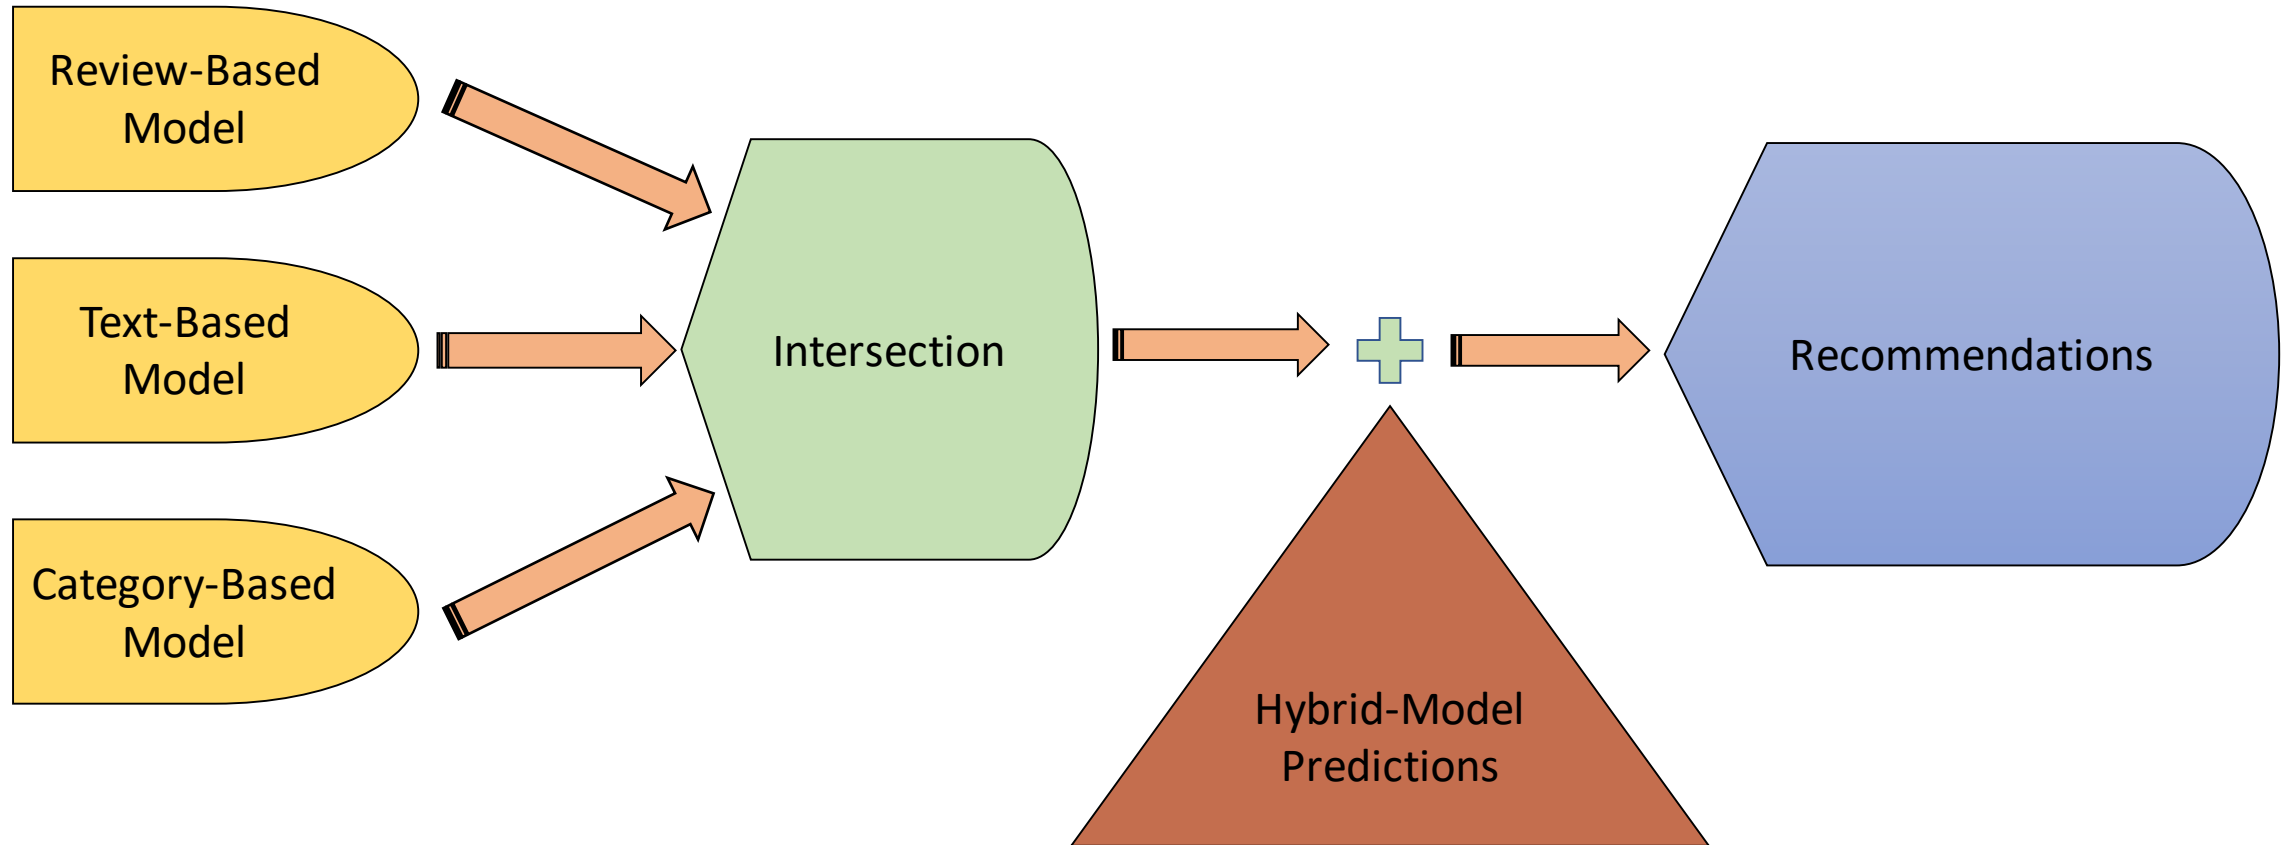

# Hybrid-Model Recommendations

top-K similar items taken from  
each Content-Based Model

common items recommended by  
all three models

Items with highest predicted  
ratings are recommended

Final recommendations for  
each user

# Subjective Analysis

## User Preferences

- Prefers Italian, pizza, or alcohol 67% of time
- Prefers price range of 1 or 2 (from 1-4) 98% of time
- Prefers restaurants who accept credit cards 100 % of time
- Prefer restaurants which are good for kids 70% of times
- Prefer restaurants with average noise level 65% of times

## User Recommendations

- 80% of restaurants recommended served Italian, pizza, or alcohol
- 100% of restaurants recommended had price range of 1 or 2
- 100% of restaurants recommended accepted credit cards
- 65% of restaurants recommended were good for kids
- 70% of restaurants recommended have average noise level

# Summary

- We implemented seven different models including 4 collaborative and 3 content based, combining them into a Hybrid Model.
- For each user, we predicted his/her rating for a restaurant as well as recommended them some restaurant that they might like.
- Finally, we analyzed that the recommendations made to each user by hybrid model were closely aligned with their preferences.

Thank You
